# Protocol Summary

---

PasswordStore is a protocol dedicated to storage and retrieval of a user's passwords. The protocol is designed to be used by a single user, and is not designed to be used by multiple users. Only the owner should be able to set and access this password.

# Disclaimer

---

The YOUR\_NAME\_HERE team makes all effort to find as many vulnerabilities in the code in the given time period, but holds no responsibilities for the findings provided in this document. A security audit by the team is not an endorsement of the underlying business or product. The audit was time-boxed and the review of the code was solely on the security aspects of the Solidity implementation of the contracts.

# Risk Classification

---

Impact		
High	Medium	Low

Impact				
	High	H	H/M	M
Likelihood	Medium	H/M	M	M/L
	Low	M	M/L	L

We use the [CodeHawks](#) severity matrix to determine severity. See the documentation for more details.

## Audit Details

The findings described in this document correspond the following commit hash:

```
2e8f81e263b3a9d18fab4fb5c46805ffc10a9990
```

### Scope

```
./src/  
└─ PasswordStore.sol
```

### Roles

- Owner: The user who can set the password and read the password.
- Outsiders: No one else should be able to set or read the password.

## Executive Summary

### Issues found

Severity	Number of issues found
High	2
Medium	0
Low	0
Info	1
Total	3

## Findings

### High

## [H-1] Storing the password on-chain makes it visible to anyone, and no longer private

**Description:** All data stored on-chain is visible to anyone, and can be read directly from the blockchain. The `PasswordStore::s_password` variable is intended to be a private variable and only accessed through the `PasswordStore::getPassword` function, which is intended to be only called by the owner of the contract.

We show one such method of reading any data off chain below

**Impact:** Anyone can read the private password, severely breaking the functionality of the protocol

**Proof of Concept:** (Proof of Code)

The below test case shows how anyone can read the password directly from the blockchain.

1. Create a locally running chain

```
make anvil
```

2. Deploy the contract to the chain

```
make deploy
```

3. Run the storage tool We use `1` because that's the storage slot of `s_password` in the contract.

```
cast storage <ADDRESS_HERE> 1 --rpc-url http://127.0.0.1:8545
```

You'll get an output that looks like this:

```
0x6d7950617373776f726400000000000000000000000000000000000000000014
```

You can then parse that hex to a string with:

```
cast parse-bytes32-string  
0x6d7950617373776f7264000000000000000000000000000000000000000014
```

And get an output of:

```
myPassword
```

**Recommended Mitigation:** Due to this, the overall architecture of the contract should be rethought. One could encrypt the password off-chain, and then store the encrypted on-chain. This would require the user to remember another password off-chain to decrypt the password. However, you'd also likely want to remove

the view function as you wouldn't want the user to accidentally send a transaction with the password that decrypts your password.

[H-2] Missing access control for `PasswordStore::setPassword` function, anybody can change the password

## Informational

[I-1] The `PasswordStore::getPassword` natspec indicates a parameter that doesn't exist, causing the natspec to be incorrect
